Summary

- Survey
 - spectroscopic and multi-wavelength
 - wide ($\sim 250\text{deg}^2$) and deep ($r_{\text{pet}} \leq 19.8, z < 0.5$)
 - uniform and high completeness (98%)
 - spectral (4.6\AA) and spatial resolution ($0.7''$)
- Science
 - Probe CDM paradigm: HMF, GSMF, Merger Rates
 - Galaxy structure and evolution

Summary

■ Methods

- Dynamical Mass

$$M \propto \sigma_v^2 R$$

- Luminosity Mass

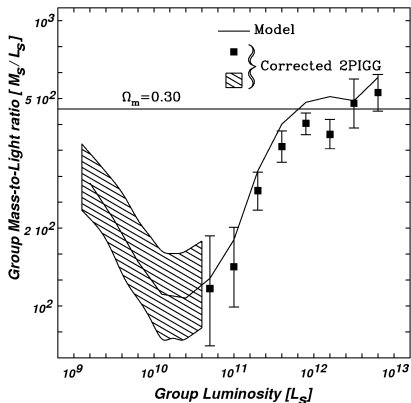

$$M \sim L$$

- Weak Lensing Mass

$$M \sim \text{distortion}$$

■ Application

- Model Mass Calibration
- M/L constraints
- HOD constraints

Summary

■ Linking shape and mass

- Observable: Ellipticity (galaxy shape)

$$e = \frac{1 - (b/a)^2}{1 + (b/a)^2}$$

- Bridge: shear (in distortion matrix) γ

In linear regime (*weak* lensing): $e \approx 2\gamma$

- Gravity defines how shear is related to the mass $\Sigma = \bar{\rho} \int \delta_m dl$ along l.o.s

$$\langle \gamma_t \rangle = \kappa(< \theta) - \langle \kappa(\theta) \rangle = \frac{\Delta \Sigma}{\Sigma_{crit}}$$

■ Mass/Density Estimators

- Surface Over-density Profile $\Delta \Sigma(r) = \frac{\sum_i w_i e_{t,i} \Sigma_{crit,i}}{2\mathcal{R} \sum_i w_i}$

- 3D Density Profile(Johnston+,07) $\Delta \rho = \frac{1}{\pi} \int_r^\infty dR \frac{-\Sigma'(R)}{\sqrt{R^2 - r^2}}$

- Aperture Mass $M_\zeta = \pi (D_l \theta)^2 \sum_i Q_i \epsilon_{t,i} \Sigma_{crit,i} / n$

- Improved $\Delta \Sigma$ and M_ζ

Summary

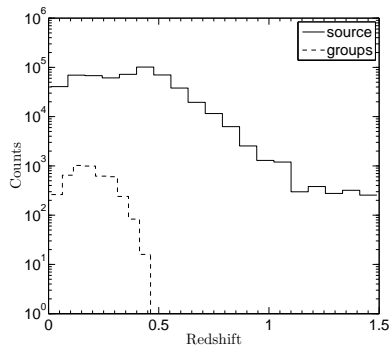

GAMA FoF groups

- 4.5k groups with $\text{Mult} > 2$
- Median-unbiased mass calibration
- Mostly $10^{13} - 10^{14} M_{\odot} h^{-1}$

SDSS source galaxies

- Re-Gaussianization shape measurements
- ZEBRA photo-z
- $1/\text{arcmin}^2$

Correction: Systematic Shear

- Ideally, no signal with randomly placed lenses.
- In practice, some systematic residual exists for random lenses.
- Need to be subtracted.

$$s \log(x) \equiv \begin{cases} \log(x) & \text{if } x > 1 \\ 0 & \text{if } |x| < 1 \\ -\log(-x) & \text{if } x < -1 \end{cases}$$

Correction: Photo-Z Dilution

Summary

- Foreground galaxies misidentified as background galaxies due to photo-z error.
- Misidentified galaxies carry no distortion, but dilutes the average signal.
- Alleviated by requiring $z_s - z_l > 0.1$, with $\Sigma_{crit}^{-2} \propto D_{ls}^2$ weighting in the shear estimator to suppress close pairs.
- Further correct for this by checking lens-source correlation.

Profile

Summary

- 1 Assume galaxies follow DM.
 - Consider one-halo term only.
- 2 Photo-z uncertainty \rightarrow PSF in z , with PSF size \gg halo size.
 $\delta z = 0.1 \sim \delta D = 300\text{Mpc}$
 - After PSF convolution, halo profile takes the shape of the PSF in the z direction.

- 3 The fraction of galaxies above given flux limit as a function of redshift is extracted from the data.

- $P \approx e^{-8.8z}$

$$n(r)/n_{rand}(r) - 1 = \alpha(\sigma_z) \frac{H(z_c)}{c} \Sigma(r)$$

Group Density
Profile

Summary

- Photo-z Calibration Bias. Compare against representative spectro-z source samples to calibrate the bias. $1\% \sim 10\%$.
- Center mis-alignment. Yet to be checked with more complete mock catalogs.
- Non-weak shear.
- Intrinsic alignment.
- ...

Error Estimation and Comparison

■ Simple Error Estimation

$$\sigma_{\Delta\Sigma}^2 = \frac{\sum_i w_i^2 \Sigma_{crit}^2 \sigma_i^2}{(\sum_i w_i)^2}$$

■ Covariance considering multiple source count

$$C_{IJ} = \frac{\sum_s \sum_{is \in I} \sum_{js \in J} w_{is} \Sigma_{crit, is} w_{js} \Sigma_{crit, js} Cov(e_{t, is}, e_{t, js})}{(\sum_s \sum_{is \in I} w_{is})(\sum_s \sum_{js \in J} w_{js})}$$

- Mento-Carlo Estimations
- Photo-z uncertainty induced error

Error Estimation and Comparison

Summary

- Stacked weak lensing analysis on GAMA groups, using SDSS shear maps
- Density profile measurement down to $10^{12}M_{\odot}h^{-1}$ groups
- Density profile fitted by NFW+linear bias model reasonably well
- Preliminary result suggests overestimated luminosity/dynamical mass
- More systematics in the fitting need to be addressed before a fair comparison with other mass observables
- Though with better quality small groups, still no significant improvement over previous measurements, due to limited sample size.
- No large scale signal for large groups due to limited survey area, and systematic shear on large scales.
- Galaxy-galaxy lensing may help utilizing the rich multiwavelength information to link against DM
